Treating Obesity with Gastric Banding

Obesity puts your health at risk

Living with excess weight has been shown to put your health at risk. The risk increases sharply as your obesity becomes more severe. Serious health problems may also result when dieting leads to “weight cycling” (the repeated loss and regain of body weight). Obesity dramatically increases the risk of type 2 diabetes, high blood pressure, high levels of triglycerides (a type of blood fat), heart disease and stroke, arthritis, and obstructive sleep apnea. Higher body weights are also associated with cancer and early death.

Bariatric surgery is the most effective treatment for obesity

Without the medical intervention that bariatric surgery provides, many patients with severe obesity are not successful in managing their weight and related health conditions. Most nonsurgical weight loss programs are based on a combination of diet, behavior modification, and regular exercise. Published scientific papers report that these methods alone rarely resolve severe obesity because they fail to help people maintain weight loss. In fact, more than 95% of people regain the weight they lose within a few years after treatment.

How it works to help you lose weight

Gastric banding is a procedure that helps you lose weight by physically changing the size of your stomach. When your stomach is smaller, it reduces the amount of food you can eat at one time. Gastric banding may also help you feel full sooner and for longer than usual. As you eat less food, your body will stop storing the excess calories and start using its fat supply for energy.

Gastric banding has been shown to resolve or improve:

- Type 2 diabetes – 20-59% resolved
- Sleep apnea – 45% resolved
- High blood pressure – 42% resolved
- High cholesterol – 71% resolved

Bariatric and metabolic surgery has helped thousands of people discover life at a healthier weight and resolve many of the health risks associated with severe obesity.

† Diabetes controlled in patients without medication. Control of diabetes is defined as HbA1c ≤7.0%.
Gastric Banding

The procedure

- The gastric band is placed around the uppermost part of the stomach to create a small upper pouch and a lower stomach.

Advantages

- Limits the amount of food that can be eaten at a meal.
- The surgery can be reversed.
- No part of the stomach or digestive system is stapled, cut or removed; food passes through the digestive tract in the usual order, allowing it to be fully absorbed into the body.
- In a clinical trial, gastric band patients lost an average of 38% of excess weight at 1 year and nearly 43% at 3 years.\textsuperscript{11}
- Shown to help resolve other conditions, such as type 2 diabetes (20-59%),\textsuperscript{3,7,8,9} obstructive sleep apnea (45%), and high cholesterol (71%).\textsuperscript{7}

Risks

The following are in addition to the general risks of surgery:

- Gastric perforation or tearing in the stomach wall may require an additional operation.
- Access port leakage or twisting may require an additional operation.
- May not provide the necessary feeling of satisfaction that one has had enough to eat.
- Nausea and vomiting
- Outlet obstruction
- Pouch dilatation
- Band migration/slippage

Talk with your surgeon about the possible surgical risks.

Gastric band adjustments

Over time, your surgeon adjusts the tightness of the band to help you continually meet your weight loss goals. During an adjustment, saline (a safe fluid) is delivered through the port into the band balloon, making the band fit more snugly around your stomach. Saline can also be removed from the band. Band adjustments take place at your surgeon's office, clinic, or hospital. Your weight, the physical symptoms you report, and other factors help your surgeon decide if a band adjustment is necessary. The timing and number of band adjustments are different for everyone and can only be determined by your surgeon.
